---

# Statistical Analysis

---

# Typical Data Science Pipeline

# Statistical Data Distributions

---

Every observed random variable has a particular frequency/probability distribution.

Some distributions occur often in practice/theory:

- The Binomial Distribution
  - The Normal Distribution
  - The Power Law Distribution
-

# Binomial Distributions

---

Experiments consist of  $n$  *identical, independent* trials which have two possible outcomes, with probabilities  $p$  and  $(1-p)$  like heads or tails.

$$P\{X = x\} = \binom{n}{x} p^x (1-p)^{n-x}$$

# Properties of Binomial Distributions

---

Discrete, but bell (or half-bell) shaped

Coin flips:  $p=0.5$   $n=200$

Lightbulb burnouts:  $p=0.001$   $n=1000$

The distribution is a function of  $n$  and  $p$ .

# The Normal Distribution

---

The bell-shaped distribution of height, IQ, etc.

Completely parameterized by mean and standard deviation:

$$f(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2 / 2\sigma^2}$$

Not all bell-shaped distributions are normal but it is generally a reasonable start.

---

# Interpreting the Normal Distribution

---

Tight bounds on probability follow for Z-scores from normally distributed random variables:

IQ is normally distributed, with mean 100 and standard deviation 15.

Thus about 2.5% of people have IQs above 130.

# Power Law Distributions

---

Power laws are defined  $P(X = x) = cx^{-\alpha}$  for exponent  $\alpha$  and normalization constant  $c$ .

They do not cluster around a mean like a normal distribution, instead having very large values rarely but consistently.

They define 80-20 rules: 20% of the  $X$  get 80% of the  $Y$ .

---

# City Population Yield Power Laws

---

The average big US city has population 165,719. Even with a huge standard deviation of 410,730, New York city with 8,008,278 people is too many sigma away from the mean.

Power laws arise when the rich get richer.

---

# Linear and Log-Log Plots for City Pop

---

Straight lines on log-log plots say power law.

The biggest values are out of scale on linear plots.

# Many Distributions are Power Laws

- Internet sites with  $x$  inlinks.
- Frequency of earthquakes at  $x$  on the Richter scale
- Words used with a relative frequency of  $x$
- Wars which kill  $x$  people

Power laws show as straight lines on log value, log frequency plots.

# When is an Observation Meaningful?

---

Computational analysis readily finds patterns and correlations in large data sets.

But when is a pattern significant?

Sufficiently strong correlations on large data sets may seem ``obviously'' significant, but the issues are often quite subtle.

---

# Comparing Population Means

---

The T-test evaluates whether the population means of two samples are different.

Sample the IQs of 20 men and 20 women. Is one group smarter on average?

Certainly the sample means will differ, but is this difference significant?

---

# Differences in Distributions

---

It becomes easier to distinguish two distributions as the means move apart...

... or the variance decreases:

# The T-Test

---

Two means differ significantly if:

- The mean difference is relatively large
- The standard deviations are small enough
- The samples are large enough

Welch's t-statistic is: 
$$t = \frac{\bar{x}_1 - \bar{x}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}}$$

where  $s^2$  is the sample variance.

Significance is looked up in a table.

# Permutation Tests and P-values

---

If your hypothesis is supported by the data, then randomly shuffled data sets should be less likely to support it.

The ranking of the real test statistic among the shuffled test statistics gives a p-value.

You need statistic on your model you believe is interesting, e.g. correlation, std. error, etc.

---

# Significance of a Permutation Test

---

The rank of the real data among the random permutations determines significance:

# The Central Limit Theorem

---

- A random variable defined as the average of a large #of independent and identically distributed(i.i.d.) random variables is itself approximately normally distributed.
- If  $x_1, \dots, x_n$  are r.v. with  $\mu$  and  $\sigma^2$ , and if  $n$  is large:  
$$Z = 1/n (x_1 + \dots + x_n)$$
 is approx. normally distributed

# Significance of central limit theorem

---

- If  $n$  gets large,  $\text{Binomial}(n, p) \sim \text{Normal}(np, np(1-p))$

# Significance of central limit theorem

---

- It implies that probabilistic and statistical methods that work for normal distributions can be applicable to many problems involving other types of distributions.

# Statistical Hypothesis Testing

---

- Example: Flipping a Coin – when speculating the coin is not fair.
    - **null hypothesis ( $H_0$ )**: coin is fair, i.e.,  $p = 0.5$
    - **alternative hypothesis ( $H_1$ )**: coin is not fair.
  - We use statistics to decide whether we can reject  $H_0$  as false or not.
    - In particular, flipping the coin  $n$  times and counting the #of heads  $X$ .
    - Each coin flip is a **Bernoulli** trial, meaning  $X$  is a **Binomial**( $n, p$ ).
    - Due to CLT,  $X$  can be approximated by **Normal**( $np, np(1-p)$ ).
    - Choose *significance* level– how willing to make a *type I error* (FP)
    - *Typical choices: 5% or 1%*
-

```
normal_two_sided_bounds(0.95, 500, 15.81) (469.01026640487555, 530.9897335951244)  
normal_two_sided_bounds(0.99, 500, 15.81) (459.27260472187146, 540.7273952781286)
```

# Types of errors

---

Table of error types		Null hypothesis ( $H_0$ ) is	
		True	False
Decision About Null Hypothesis ( $H_0$ )	Reject	Type I error (False Positive)	Correct inference (True Positive)
	Fail to reject	Correct inference (True Negative)	Type II error (False Negative)

Type I error is detecting an effect that is not present, while a type II error is failing to detect an effect that is present.

---

# Visualizing Data

---

# Typical Data Science Pipeline

# Exploratory Data Analysis

“The greatest value of a picture is when it forces us to notice what we never expected to see.”

John Tukey

# Exploratory Data Analysis

---

Looking carefully at your data is important:

- to identify mistakes in collection/processing
- to find violations of statistical assumptions
- to observe patterns in the data
- to make hypothesis.

Feeding unvisualized data to a machine learning algorithm is asking for trouble.

---

# Anscombe's Quartet

---

All four data sets have exactly the same mean, variance, correlation, and regression line:

	I		II		III		IV

# Tufte's Design Principle

---

Distinguishing good/bad visualizations requires a design aesthetic, and a vocabulary to talk about data representations:

- Maximize data ink-ratio
  - Minimize lie factor
  - Minimize chartjunk
  - Use proper scales and clear labeling
-

# Maximize Data-Ink Ratio

---

$$\text{Data-Ink Ratio} = \frac{\text{Data ink}}{\text{Total ink used in graphic}}$$

# Maximize Data-Ink Ratio

# Reduce Chartjunk

---

Extraneous visual elements distract from the message the data is trying to tell.

- Extra dimensionality
- Uninformative coloring
- Excessive grids and figurative decoration

In an exciting graphic, the data tells the story, not the chartjunk.

# Scatter Plots / Bubble Charts

---

- Scatter plots show the values of each point, and are a great way to present 2D data sets.
  - For data sets with three or four variables, use bubble charts.
  - Higher dimensional datasets can be projected to 2D through principle component analysis.
